MovieWatch: A Web-Based Movie Watchlist Application

MovieWatch is a web-based software application designed to help users organize and keep track of movies they want to watch or have already watched. The purpose of this application is to provide users with a simple and convenient way to maintain a personal movie watchlist in one central location. Users will be able to add movies to their watchlist and store information such as the movie title, genre, and release year. The application will also allow users to update or remove any movies as their watchlist is altered. This will provide a structured alternative to manually keeping track of movies through notes or other separate applications.

The main users of MovieWatch will be individuals who frequently watch movies and want an organized way to manage their viewing choices. The application will provide a graphical user interface (UI) that allows users to interact with their movie collection. Users will be able to add movies through an input form and view their saved movies through the main watchlist interface. The application will also provide search and filtering functionality so users can easily locate their movies based on specifications such as title or genre. Users will also be able to mark their movies as “Watched” or “Want to Watch” which will allow them to easily distinguish between movies they’ve completed and movies they plan to watch.

MovieWatch will use a database to store and manage all information entered by users. This database connection will be used to create, retrieve, update, and delete movie records. Using a database is important because it allows all movie information to be stored safely and continuously instead of being deleted whenever the application is closed. This will also make it possible for the application to manage a larger amount of movie records as the user’s watchlist increases.

The application will be developed using HTML, CSS, and JavaScript for the user interface, Python with Flask for the backend, and SQLite for the database. HTML and CSS will be used to structure and design the application’s pages, while JavaScript will be used to provide interactive features and improve the user’s experience whenever they interact with the application. Flask will be used to connect the user interface to the application’s backend and database. SQLite will be used because it is a lightweight relational database that can store the movie records without needing any separate database server.

Overall, MovieWatch will provide users with a centralized and simple way to manage their movie watchlists. The combination of a graphical user interface, backend functionality, and database connection will allow the application to meet the necessary requirements of a complete software application while still providing useful functionality for its intended users.
